Encoders and decoders

Encoders

$2^n = n$ ∴ 3 is input and 8 is output

$2^3 = 8$

→ An encoder is a combinational circuit that perform the reverse operation of DECODERs. It has maximum of 2^n input lines and (n) output lines. It will products a binary code equivalent to the input, which is active high. Therefore the ENCODER, ENCODE 2^n input line with in small n bits. It is optional to represent the enable signal in ENCODERS.

$2^n =$

* It is well known that a binary to octal decoder (3-to-8 decoder) accep : s a 3-bit input code and activities one of eight output lines corresponding to that code. An octal-to-binary encoder perform the opposite function, it accepts eight inputs and produces a 3-bit output code corresponding to the activated input.

~~3.~~) Decimal-to-BCD Encoder (10 – 4)

A decimal-to-BCD encoder is one with ten iputs corresponding to ten decimal digits (0 to 9) and four outputs (A, B, C, D) representing the BCD value of input decimal digit.

Priority Encoder :-

The priority encoder is an encoder that includes the priority function. The operation of the priority encoder is such that if two or more inputs are equal to 1 at the same time, the input having the highest priority will take precedence. The truth table of a four-input priority encoder is:-

Decoder

→ A decoder is similar to demultiplexer but without any data input most digital system required the decoding of data. Decoding is necessary in application such as data demultiplexing, digital display, digital to analog converters and memory addressing.

A decoder is a logic circuit that converts an n-bit binary input code into 2^n = output lines. such that each output line will be activated four only one of possible combination of inputs.
